Employee ID Management System using BST

Problem Statement

Managing employee records is an important task in every organization. As the number of employees increases, storing, searching, and displaying employee information efficiently becomes necessary.

The aim of this project is to develop an Employee ID Management System using a Binary Search Tree (BST) in C++. The system stores each employee's unique ID along with their name and allows users to insert, search, and display employee records.

The system also provides an option to display employee records in ascending order of their IDs and counts the number of comparisons performed during an employee search. Duplicate employee IDs are not allowed.

By using a Binary Search Tree, employee records can be organized systematically, making searching and data management easier.
