

PROBLEM STATEMENT

Train Coach Management Using Circular Linked List in C++

Develop a Train Coach Management System using a Circular Linked List in C++. The system should allow users to add new coaches, remove existing coaches, display all coaches, and search for a particular coach using its coach number or type. Each coach should be represented as a node containing coach details and a pointer to the next coach. The last coach must point back to the first coach, forming a circular linked list. The system should provide a menu-driven interface to manage coach operations efficiently and demonstrate the practical application of circular linked lists in train coach management.
